MAXMETRICS · YOUR FORCE RESULTS

How your lower body produced force

Sam, this page is written for you, not for a lab. We measured how hard and how quickly you could push into the force plates on 12 September 2026. The full numbers are stored in your file. Here is what they mean in everyday language.

YOUR STRONGEST EFFORT

0.70 × your bodyweight

You produced 0.70 times your bodyweight (60.9 kg). That is a simple way to describe your strength today. We will compare it with your next test rather than guessing a population ranking.

LEFT AND RIGHT

47% / 53%

one side did a little more of the work. Left contributed 47% and right contributed 53% (12.5% difference). A difference at or under 10% is our in-house target, not a medical diagnosis.

How quickly the force showed up

In the first 200 milliseconds you reached 23.5 kg — about 39% of your peak force. That is about how quickly the force showed up, not how strong you are overall.

What you should work on

- Help the left side contribute more during two-legged work. Think even pushing, not “a weak left quad”.
- Practise producing force quickly, not only as hard as possible. Short, sharp lower-body efforts are a useful next step.
- Keep building whole-body strength so the next retest shows a higher force for your bodyweight.

Why this matters

Being able to produce force with your legs helps you walk with confidence, get up from a chair, climb stairs, and stay capable as you age. Speed of force matters when you need to catch yourself or change direction.

Isometric Mid-Thigh Pull

This is a standing pull. You tried to produce as much lower-body force as you could, without a jump.

Sam, here is the simple version. This is a standing pull. You tried to produce as much lower-body force as you could, without a jump. Your best effort was 0.70 times your bodyweight. Left and right split the work 47:53.

Peak force	60.9 kg
Relative force	0.70 × bodyweight
Force at 200 ms	23.5 kg
Left / right	47% / 53%
Asymmetry	12.5%

Isometric Deadlift

This is a standing pull from a deadlift position. It shows how much force you can produce through your hips and lower body.

Sam, here is the simple version. This is a standing pull from a deadlift position. It shows how much force you can produce through your hips and lower body. Your best effort was 1.34 times your bodyweight. Left and right split the work 41:59.

Peak force	117.5 kg
Relative force	1.34 × bodyweight
Force at 200 ms	25.0 kg
Left / right	41% / 59%
Asymmetry	30.0%

Soleus Test

This looks at force from the lower leg. It is not a measure of every muscle in the thigh.

Sam, here is the simple version. This looks at force from the lower leg. It is not a measure of every muscle in the thigh. Your best effort was 0.55 times your bodyweight. Left and right split the work 46:54.

Peak force	47.9 kg
Relative force	0.55 × bodyweight
Force at 200 ms	16.3 kg
Left / right	46% / 54%
Asymmetry	13.9%
